

Vector-valued Gaussian Processes

Andrew Moore, Grady Wright (Department of Mathematics)

Keywords — Gaussian Processes, Statistics, Velocity Fields

I. Overview of Gaussian Processes

Gaussian processes generalize the multivariate Gaussian distribution and can be used to describe a probability distribution over families of functions.

i. Multivariate Gaussian Distribution

The multivariate Gaussian distribution is used to model *random* vectors (vectors of jointly distributed random variables).

$$egin{aligned} oldsymbol{x} \in \mathbb{R}^N &\sim \mathcal{N}_N(oldsymbol{\mu}, oldsymbol{\Sigma}) \\ oldsymbol{\mu} \in \mathbb{R}^N &= (\mu_1, \mu_2, ..., \mu_N)^\top = (\mathbb{E}(x_1), \mathbb{E}(x_2), ..., \mathbb{E}(x_N))^\top \\ oldsymbol{\Sigma} \in \mathbb{R}^{N \times N} &= \mathbb{E}\left((oldsymbol{x} - oldsymbol{\mu})(oldsymbol{x} - oldsymbol{\mu})^\top\right) = \left[\operatorname{cov}(x_i, x_j)\right]_{i,j=1}^N \end{aligned}$$

$$x_i \sim \mathcal{N}(\mu_i, oldsymbol{\Sigma}_{ii})$$

ii. Gaussian Processes (GPs)

- Gaussian process (GP): an uncountably infinite collection of random variables; any finite sample is a draw from a MV Gaussian distribution.
- GPs are fully specified by a mean function m and covariance (kernel) function k.
- The kernel function must produce a positive semi-definite matrix when evaluated on a set of input points (or vectors).

We focus on the *squared exponential kernel* $k : \mathbb{R}^p \times \mathbb{R}^p \to \mathbb{R}$, defined as:

$$k(x, x') = \alpha^2 \exp\left(-\frac{1}{2\rho^2} \|x - x'\|^2\right).$$
 (2)

- $\|\cdot\|$ is the Euclidean Norm: $\|m{x}\| = \sqrt{x_1 + x_2 + \dots + x_N}$
- α and ρ are *hyperparameters* (chosen, or estimated from data)

II. Gaussian Process Regression – Univariate y

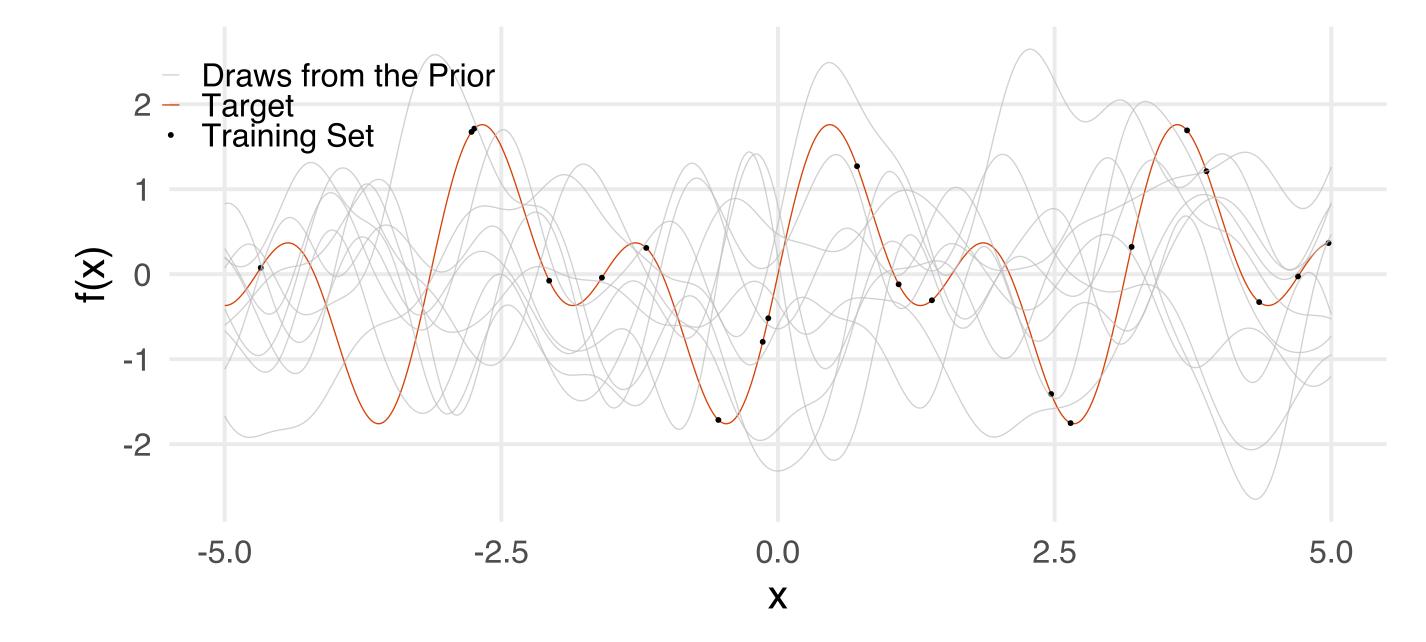

Let $S=(\boldsymbol{x},\boldsymbol{y})=\{(x_i,y_i):x_i\in\mathbb{R}^p,y_i\in\mathbb{R}^d,i\in 1,2,...,N\}$ be a researcher's dataset, and let N=20 and M=400-N. We wish to use S to find an unknown function f that satisfies $\boldsymbol{y}=f(\boldsymbol{x})$, possibly subject to additive noise ε . We can draw samples from the prior distribution:

$$f \sim \mathcal{GP}(\mathbf{0}, k)$$

$$\mathbf{y}_* \sim \mathcal{N}_M(\mathbf{0}, k(\mathbf{x}_*, \mathbf{x}_*))$$

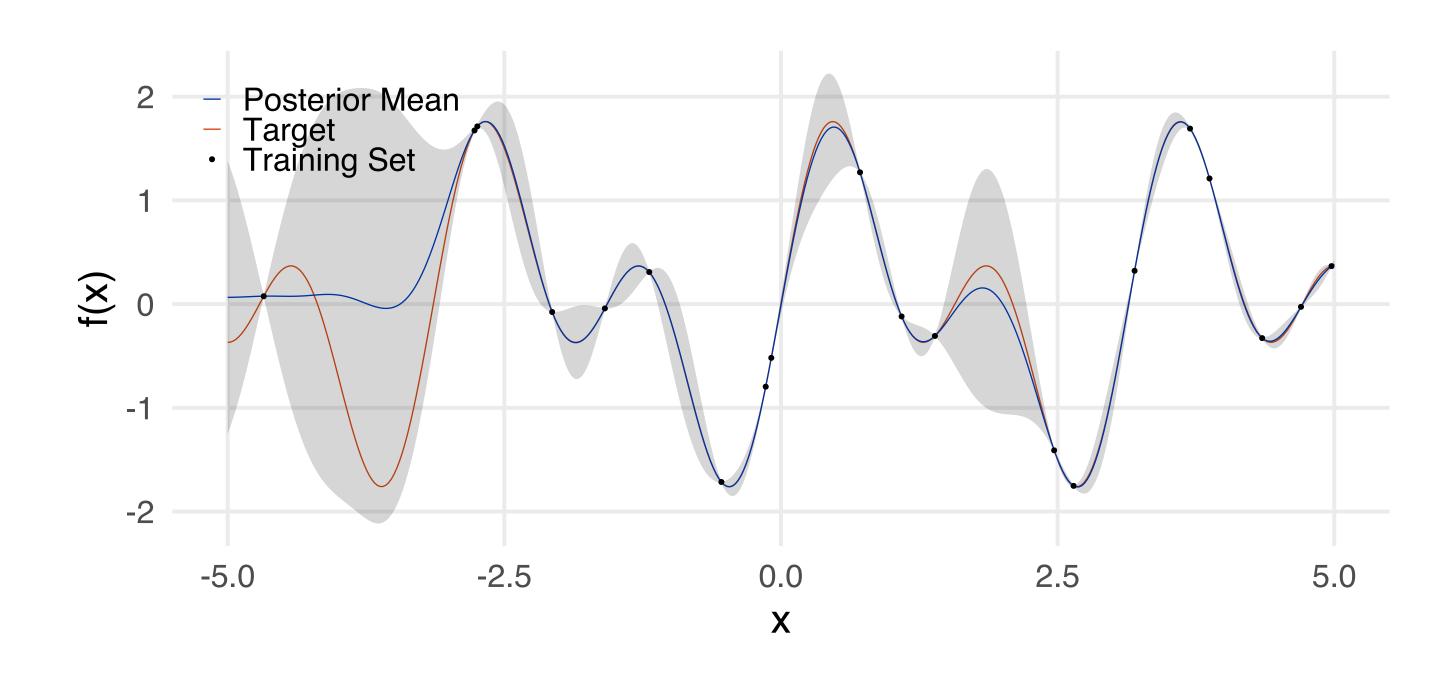

$$k(\mathbf{x}_*, \mathbf{x}_*) \in \mathbb{R}^{M \times M} = \left[k(\mathbf{x}_{*i}, \mathbf{x}_{*j})\right]_{i, j=1}^{M}.$$
(3)

- Draws from the prior distribution (shown in grey) don't necessarily agree with the data points.
- Kernel choice determines properties of f (e.g., smoothness)

Our prior model for f and the observed data S can be combined to form a *posterior* distribution:

$$\begin{aligned} \boldsymbol{y}_* \mid \boldsymbol{x}, \boldsymbol{y}, \boldsymbol{x}_* &\sim \mathcal{N}_M \big(\hat{\mu}, \hat{\Sigma} \big) \\ \hat{\mu} \in \mathbb{R}^M &= k(\boldsymbol{x}_*, \boldsymbol{x}) (k(\boldsymbol{x}, \boldsymbol{x}))^{-1} \boldsymbol{y} \\ \hat{\Sigma} \in \mathbb{R}^{M \times M} &= k(\boldsymbol{x}_*, \boldsymbol{x}_*) - k(\boldsymbol{x}_*, \boldsymbol{x}) (k(\boldsymbol{x}, \boldsymbol{x}))^{-1} k(\boldsymbol{x}_*, \boldsymbol{x})^{\top}_{(4)} \\ k(\boldsymbol{x}, \boldsymbol{x}) \in \mathbb{R}^{N \times N} &= \left[k \big(\boldsymbol{x}_i, \boldsymbol{x}_j \big) \right]_{i,j=1}^N \\ k(\boldsymbol{x}_*, \boldsymbol{x}) \in \mathbb{R}^{M \times N} &= \left[k \big(\boldsymbol{x}_{*i}, \boldsymbol{x}_j \big) \right]_{i,j=1}^{M,N}. \end{aligned}$$

III. Multioutput GPR – Vector-valued y

- GPR can be extended to targets with >1 dimensions.
- Velocity fields: $oldsymbol{X}, oldsymbol{Y} \in \mathbb{R}^{N imes 2}$
- ullet Idea: columns of $oldsymbol{Y}$ might not be independent
- Intrinsic Coregionalization Model (ICM): combines the kernel matrix with a similarity matrix ${\cal B}$
